This work derives from and formalizes the inter-Self coordination architecture introduced in “Inter-Self Coordination via Shared Substrate / Full Aspect Integration” (Li, April 2026), the third paper in the CKS theory series following “Coordination Outside the Model: A Human-Governed Substrate Pattern for AI Systems” (Li, April 2026) and “The Instinct/Reasoning Separation Outside the Model” (Li, April 2026).

Abstract

This note formalizes the governance requirements that arise when Emergency Dissolution (D2.28) and Configuration Governing Evolution Feed (D2.52) apply simultaneously to a single Full Aspect Integration (FAI) event. Three non-obvious requirements emerge from this composition: evolution feed governance continues to apply under emergency dissolution without suspension; pre-authorization of evolution feed configuration is the architectural resolution to the tension between compressed emergency timelines and governed feed operation; and each of D2.28’s dissolution triggers affects shared-substrate content differently, making trigger-dependent documentation of feed completeness a compositional requirement. The third trigger — exchange bounding violation — requires a pre-specified exclusion override as the one case where emergency circumstances must modify the pre-configured eligibility scope.

1. Pair Identification

Commitment A — Emergency Dissolution (D2.28) governs FAI events that must end before their planned dissolution time. The commitment specifies five requirements: a dissolution trigger from among a defined set of causes, a compressed governance timeline for completing the dissolution process, documented handoff of shared-substrate content at the dissolution boundary, record-keeping of the emergency event, and notification to participating Selves. The defining feature of D2.28 is the compressed timeline: governance must act faster than the standard dissolution protocol permits.

Commitment B — Configuration Governing Evolution Feed (D2.52) governs what flows from the shared substrate to each participating Self's home evolution machinery at dissolution. The commitment specifies five configured objects: eligibility scope (what content qualifies for the evolution feed), exclusion conditions (what content is excluded regardless of scope), routing instructions (which home evolution mechanism receives which content), carry-through annotations (how preserved conflicts and escalation records annotate the feed), and feed-authorization record (the governance artifact confirming the feed proceeded under the pre-configured eligibility). The defining feature of D2.52 is that the evolution feed is a governed act, not an automatic data transfer.

The composition arises whenever an FAI event undergoes emergency dissolution: Commitment A compresses the governance timeline, and Commitment B requires that governance-configured evolution feed eligibility govern the dissolution handoff. Both commitments apply simultaneously to the same event.

2. Governance Scenario Requiring Both Simultaneously

An active FAI event has been operating under its standard governance configuration. Mid-event, a condition triggers emergency dissolution under D2.28. Governance must execute dissolution under compressed timelines — the cause may be a governance capacity failure, an escalation failure, an exchange bounding violation, a participating Self's home governance withdrawal, or a joint-authority determination that the event cannot complete safely.

At the same moment, D2.52 applies: whatever content is in the shared substrate at dissolution time must flow to participating Selves' home evolution machinery per the configured eligibility scope, exclusion conditions, routing instructions, and carry-through annotations. The evolution feed does not pause because dissolution is happening under emergency conditions. The feed is triggered by dissolution itself — whether that dissolution is planned or emergency is not a variable D2.52 conditions upon.

The scenario thus requires governance to satisfy two commitments under a single compressed window: execute the emergency dissolution per D2.28's five requirements, and execute the evolution feed per D2.52's five configured objects. Neither commitment addresses the other's presence. The compositional requirements are invisible until both apply at once.

3. Non-Obvious Governance Requirements from the Combination

Requirement 1 — Evolution feed governance applies under emergency dissolution without suspension.

The compressed timeline of emergency dissolution does not waive D2.52's authority. Governance cannot defer the evolution feed pending the conclusion of emergency review, because dissolution is itself the event that triggers the feed. Whatever is in the shared

substrate when dissolution executes flows to home evolution machinery per the configured eligibility scope. This means governance must have made its evolution feed eligibility decisions before any emergency arises — not at the moment of emergency dissolution. The composition makes this forward-looking governance requirement visible; neither commitment alone states it.

Requirement 2 — Pre-authorization is the composition's resolution.

Under planned dissolution, governance has time to review evolution feed candidates and confirm the feed configuration before authorizing the handoff. Under emergency dissolution, that review time is unavailable by definition. The composition creates a structural choice: proceed with the evolution feed under the pre-configured eligibility scope without real-time review, or halt the evolution feed pending review and lose the governance value of the FAI event's work. The architectural resolution is pre-authorization.

Pre-authorization means the evolution feed eligibility scope — D2.52's Configured Object 1 — must be designed to be valid under emergency conditions, not only under planned dissolution. The standing configuration (D2.21) or the event configuration (D2.12) must explicitly address what the evolution feed eligibility scope means when dissolution is triggered by an emergency cause. When pre-authorization is in place, governance proceeds with the feed as a pre-authorized act: the eligibility decision has already been made, the configured objects already specify the feed's boundaries, and no real-time review is required. The feed-authorization record (D2.52's Configured Object 5) documents that the feed proceeded under pre-authorized configuration. Without pre-authorization, governance has no legitimate basis for proceeding with the feed, and the event's collaborative content is lost.

Requirement 3 — Trigger-dependent content affects evolution feed completeness.

The five triggers for emergency dissolution under D2.28 are not equivalent with respect to the shared substrate's content state at dissolution time. Each trigger leaves the substrate in a distinct condition, which directly affects what the evolution feed can deliver.

When dissolution is triggered by governance capacity failure (Trigger 1), content in the shared substrate may be substantially complete but unreviewed. The evolution feed can proceed under the pre-configured eligibility scope without structural modification; the primary documentation requirement is that the unreviewed status be noted in the carry-through annotations.

When dissolution is triggered by escalation failure (Trigger 2), the substrate includes pending escalated conflicts that were never resolved. These pending escalations carry through as annotations in the evolution feed per D2.52's Configured Object 4, flagging boundaries that participating Selves' home governance must address. The feed can proceed, but feed completeness is affected: recipients must know that certain content arrives carrying unresolved escalation annotations rather than resolved outputs.

When dissolution is triggered by exchange bounding violation (Trigger 3), the substrate may contain out-of-bounds content — content that was introduced during the event in violation of the exchange bounding commitment. This content must be excluded from the evolution feed regardless of what the pre-configured eligibility scope would otherwise permit. The composition requires that Trigger 3 carry a pre-specified exclusion override: D2.52's Configured Object 2 (exclusion conditions) must include an explicit provision that out-of-bounds content identified at the time of a bounding violation is excluded from the evolution feed pending the violation investigation. This is the one case where the pre-configured eligibility scope is overridden by an emergency-specific exclusion condition — and the architectural requirement is that even this override be pre-specified, not ad hoc, so that the exclusion itself is a governance act rather than an emergency decision.

The governance record for any emergency dissolution must identify which trigger was active and document how it affected evolution feed completeness. Participating Selves cannot correctly interpret what their evolution feed received without knowing whether content is absent, annotated with unresolved escalations, or reduced by bounding violation exclusions. This documentation requirement is invisible from either commitment alone; it emerges only from their composition.

4. Prior-Art Significance

Any governed AI coordination system that includes both an emergency shutdown mechanism and a learning-preservation mechanism faces the compositional requirements this note formalizes. The questions are not system-specific: Does emergency shutdown suspend learning preservation, or does pre-authorized configuration resolve the tension? Does the shutdown cause affect the completeness of what learning preservation receives? Does bounding violation require exclusion logic that overrides the standard learning scope?

These questions arise at the intersection of two independently-specified commitments. Systems that address each commitment in isolation, without specifying their interaction, leave these questions open. The three requirements formalized here — feed governance without suspension, pre-authorization as resolution, and trigger-dependent completeness documentation — are specific governance requirements of this composition. Any system that claims to satisfy both an emergency dissolution commitment and an evolution feed commitment must address all three, whether or not it does so explicitly. The failure modes (evolution feed halted at dissolution, pre-authorization absent, trigger documentation omitted, Trigger 3 exclusion left to ad hoc decision) are distinct and independently realizable.

5. Operational Test

For an emergency dissolution event, an observer with access to the governance record and the evolution feed output should be able to verify three things.

First, the evolution feed should have proceeded under the pre-configured eligibility scope without real-time governance review. The feed-authorization record should identify which standing or event-level configuration authorized the feed, and should confirm that no real-time review was conducted — that the feed proceeded as a pre-authorized act. If the governance record instead shows the feed was halted pending review, or that an ad hoc eligibility decision was made at the time of dissolution, the pre-authorization requirement has not been satisfied.

Second, the emergency dissolution record should identify which of D2.28's dissolution triggers was active and should document how that trigger affected evolution feed completeness. For Trigger 1, the record should note that content was unreviewed at dissolution. For Trigger 2, the record should identify which escalations were pending and confirm they carried through as feed annotations. For Trigger 3, the record should identify what out-of-bounds content was present and confirm it was excluded from the feed pending violation investigation.

Third, for Trigger 3 specifically, the evolution feed output should not contain any content identified as out-of-bounds at the time of the bounding violation. The exclusion should be traceable to D2.52's exclusion conditions configured object, not to an ad hoc decision made at dissolution time. If the exclusion cannot be traced to pre-specified exclusion logic, the Trigger 3 override requirement has not been satisfied.

All three verifications are observable from the governance record and the feed output. A system that passes all three has satisfied the compositional requirements of Emergency Dissolution and Configuration Governing Evolution Feed operating simultaneously.
