This work derives from and formalizes the inter-Self coordination architecture introduced in “Inter-Self Coordination via Shared Substrate / Full Aspect Integration” (Li, April 2026), the third paper in the CKS theory series following “Coordination Outside the Model: A Human-Governed Substrate Pattern for AI Systems” (Li, April 2026) and “The Instinct/Reasoning Separation Outside the Model” (Li, April 2026). It does not introduce new axioms. Its contribution is to identify the four governance provisions that a cross-organizational agreement must contain when the FAI relationship it governs operates at high frequency, and to formalize why the combination of D2.71 and D2.34 generates requirements neither commitment generates alone.

Abstract

Two Paper 3 operational commitments compose in a governance-critical way when they appear together. D2.71 addresses high-frequency FAI event governance: the infrastructure, review cadence, and monitoring disciplines required when two coordinating organizations conduct Full Aspect Integration events at daily or weekly cadence rather than on a periodic or ad hoc schedule. D2.34 addresses the cross-organizational governance agreement: the five-component bilateral framework that governs the ongoing FAI relationship between two organizations — mutual governance standards, escalation framework, configuration policy, amendment protocol, and dissolution terms. Each commitment is individually coherent. Their composition, however, generates four non-obvious requirements that neither commitment surfaces on its own. A cross-organizational governance agreement applied to a high-frequency FAI relationship must explicitly acknowledge high-frequency governance practices as compliant alternatives; must specify escalation overflow procedures; must accommodate learning-driven amendment velocity; and must include a governance health remediation clause. An agreement that satisfies D2.34 without these four provisions will produce systemic non-compliance when the FAI relationship it governs operates at high frequency. This note identifies the composition, derives the four requirements, and provides an operational test for detecting their presence or absence in any candidate agreement.

1. The pair and the governance problem it creates

D2.71 and D2.34 address different governance concerns. D2.71 addresses operational tempo: when FAI events are conducted daily or weekly, per-event governance disciplines — post-mortem review after every event, manual escalation monitoring, amendment cycles driven by accumulated quarters of data — become structurally impractical. High-frequency governance responds with sampled post-mortem review, automated governance labor covering health monitoring and routine escalation routing, and amendment cycles triggered by observed standing-configuration problems rather than by calendar. D2.34 addresses relationship structure: when two organizations enter an ongoing FAI relationship, the bilateral governance framework that makes the relationship durable and auditable is a five-component agreement covering what governance standards each party commits to, how escalations will be handled across the organizational boundary, how configuration decisions will be made, how the agreement will be amended over time, and under what conditions the relationship ends.

The governance problem arises when D2.34 is instantiated without D2.71 in view. Cross-organizational governance agreements are typically written from low-frequency assumptions. The mutual governance standards in Component 1 specify what each party commits to doing for each FAI event. The escalation framework in Component 2 specifies a response timeline, implicitly assuming a bounded and manageable escalation volume. The amendment protocol in Component 4 specifies a review cycle, implicitly assuming that the time between amendments is measured in quarters. These specifications are appropriate for a low-frequency FAI relationship — one where events occur monthly or less frequently. Applied to a high-frequency relationship, each of them converts into a source of structural non-compliance. The partner operating at high frequency is not failing to comply with the agreement; the agreement was written for a different operational tempo, and that tempo mismatch is the failure mode.

The composition of D2.71 and D2.34 requires that the agreement explicitly account for high-frequency operations in four of its five components. The requirement is not that the agreement be rewritten from scratch; it is that specific provisions be added that the low-frequency template does not naturally contain.

2. Requirement 1 — Component 1 must explicitly acknowledge high-frequency governance practices as compliant alternatives

Component 1 of the cross-organizational governance agreement establishes mutual governance standards: what each party commits to maintaining as its home governance discipline as a condition of the ongoing FAI relationship. In a low-frequency relationship, standard governance practice includes a full post-mortem review after each FAI event, manual monitoring of governance health between events, and human-reviewed escalation handling for every escalation that arises. These are reasonable commitments when events occur monthly or less frequently.

At high frequency, these same commitments produce structural non-compliance in normal operation. An organization conducting FAI events daily that has committed to a full post-mortem after each event must conduct post-mortems faster than they can be meaningfully processed. The commitment is not violated by bad faith; it is violated by the operational arithmetic of the schedule. The same applies to manual governance monitoring: at high frequency, the volume of monitoring data exceeds what periodic manual review can track, and automated monitoring is not a shortcut but a governance necessity.

The composition requirement is that Component 1 explicitly enumerate high-frequency governance practices — sampled post-mortem review rather than per-event review, automated governance labor for health monitoring and routine escalation routing — as practices that satisfy the mutual governance standards. Enumeration matters here: it is not sufficient for the agreement to be silent about review cadence and leave each party to infer what is acceptable. Silence in Component 1 defaults to per-event review in most governance frameworks, which means silence creates the same structural non-compliance as an explicit per-event requirement when applied to high-frequency operations. The high-frequency partner must be able to point to a specific provision in Component 1 that names its actual practices as compliant.

3. Requirement 2 — Component 2 must specify escalation overflow procedures

Component 2 of the cross-organizational governance agreement establishes the escalation framework: the pathway by which escalations arising during FAI events are surfaced across the organizational boundary to joint human authority, and the timeline within which each party commits to responding. In a low-frequency relationship, simultaneous escalations are exceptional. The escalation framework can specify a single response timeline because the typical case is a bounded queue.

At high frequency, simultaneous escalations are not exceptional. They are a statistical feature of the operational tempo. An organization conducting daily FAI events will regularly encounter periods where multiple escalations are open simultaneously — some from the current event, some from prior events not yet resolved, some triggered by governance health monitoring detecting threshold crossings across multiple dimensions at once. An escalation framework that specifies only a response timeline, without procedures for the simultaneous-escalation case, will encounter its failure condition as normal operations rather than as edge cases.

The composition requirement is that Component 2 specify escalation overflow procedures: how escalations are queued when simultaneous escalations exceed the specified handling capacity; what the maximum response timeline is for a queued escalation (distinct from the standard response timeline for an unqueued escalation); and what happens when escalation volume exceeds the queue's capacity — specifically whether event frequency reduction is available as an immediate governance response to escalation overload. This last provision links to Requirement 4: event frequency reduction connects the escalation framework to the governance health remediation

clause, so that a sustained escalation overflow is not merely a compliance problem but a signal that triggers formal remediation procedures.

4. Requirement 3 — Component 4 must accommodate learning-driven amendment velocity

Component 4 of the cross-organizational governance agreement establishes the amendment protocol: how the agreement's configuration parameters are reviewed and updated over time as the FAI relationship matures and as both parties accumulate experience operating under the agreement. In a low-frequency relationship, the natural rhythm of amendment is quarterly or annual: each period accumulates a modest number of events and the associated governance data, which the amendment review cycle synthesizes into standing-configuration improvements.

High-frequency operations accelerate this learning curve. More FAI events per period means more post-mortems per period, more governance health data per period, and faster identification of standing-configuration improvements — sharing scope settings that are consistently suboptimal, escalation thresholds calibrated for a tempo that has since changed, configuration parameters that were reasonable at the relationship's inception but have been revealed as friction sources by accumulated operational experience. An amendment protocol specifying quarterly review will regularly find itself holding a backlog of identified improvements that the quarterly cadence cannot absorb.

The composition requirement is that Component 4 specify an amendment velocity appropriate for high-frequency learning: either a shorter amendment review cycle than the quarterly default, or an event-triggered amendment mechanism that allows amendments to be proposed and processed outside the scheduled review cycle when operational experience identifies a clear standing-configuration improvement. The event-triggered option is often more practical: it avoids the overhead of a permanently accelerated review cycle while preserving the ability to act quickly when high-frequency operations surface problems that should not wait for the next scheduled review. The specific cadence is configuration-dependent; the requirement is that the amendment protocol explicitly address it rather than defaulting to a low-frequency template.

5. Requirement 4 — A governance health remediation clause must be present

Governance health monitoring for high-frequency FAI operations, addressed by D2.35, produces a stream of health measurements. These measurements detect whether the governance disciplines both parties have committed to — sampled post-mortem completion rates, escalation response compliance, configuration stability — are holding over time or degrading under the operational load of sustained high-frequency events. Without a governance health remediation clause in the cross-organizational agreement, this monitoring stream produces measurements but no obligations. Both parties can observe governance health degradation, and the agreement is silent on what either party must do in response.

The composition requirement is a governance health remediation clause that specifies three things. First, notification obligations: when health monitoring detects degradation below agreed thresholds, which party notifies which, in what form, and within what timeline. Second, a remediation timeline: once notification has been issued, the period within which the degrading party commits to restoring health to acceptable levels. Third, event frequency reduction as an available governance remedy: if health cannot be restored to acceptable levels at the current FAI event frequency, the agreement explicitly authorizes a reduction in event frequency as a governance action, not a relationship failure. This last element is what makes the clause a remediation mechanism rather than merely a termination trigger. A clause that specifies notification and remediation timeline without the frequency reduction option converts every governance health crisis into an all-or-nothing choice between full compliance at the current tempo or dissolution of the relationship. The frequency reduction option preserves the relationship while creating a formal governance pathway to restore health — which is the outcome both parties typically prefer.

The remediation clause also closes a loop that the agreement otherwise leaves open. Without it, governance health degradation below agreed thresholds is simultaneously a technical fact (measured by D2.35 monitoring) and a governance nullity (generating no formal obligation under the agreement). The clause converts the technical fact into a governance obligation, making the agreement responsive to the operational signals that high-frequency operations reliably generate.

6. Prior-art significance

The four requirements derived in this note — acknowledged high-frequency practices in Component 1, escalation overflow procedures in Component 2, learning-driven amendment velocity in Component 4, and a governance health remediation clause as an additional requirement — are specific to the composition of D2.71 and D2.34. None of them is a general requirement of cross-organizational governance agreements; each is a requirement generated by the operational tempo that D2.71 defines.

Any architecture claiming to provide a “sustained high-frequency AI coordination governance agreement” must address these four requirements. An agreement satisfying D2.34 without them is not wrong as a governance framework; it is mismatched to the operational tempo it is supposed to govern. The mismatch is structural: it will produce regular violations of the agreement’s own terms under normal high-frequency operations, not under exceptional or adversarial conditions. This is the prior-art significance of the composition. The four provisions formalized here define what distinguishes a governance agreement designed for high-frequency operations from one designed for low-frequency operations and applied to high frequency without adjustment.

7. Operational test

For a cross-organizational FAI relationship operating under a governance agreement and conducting FAI events at high frequency, an observer can verify the composition requirements by

inspecting the agreement for the following:

(a) *Component 1 acknowledgment*. Does Component 1 of the agreement explicitly enumerate sampled post-mortem review (rather than requiring per-event review) and automated governance labor for health monitoring and routine escalation routing as governance practices that satisfy the mutual governance standards? If Component 1 specifies per-event review without a high-frequency alternative, or is silent about review cadence, this requirement is not satisfied.

(b) *Component 2 overflow specification*. Does Component 2 of the agreement specify: a queue management procedure for simultaneous escalations; a maximum response timeline for queued escalations distinct from the standard timeline; and an overflow procedure that identifies event frequency reduction as an available immediate response to sustained escalation overload? If Component 2 specifies only a response timeline without overflow provisions, this requirement is not satisfied.

(c) *Component 4 amendment velocity*. Does Component 4 of the agreement specify either a review cycle shorter than the quarterly default or an event-triggered amendment mechanism allowing standing-configuration improvements to be proposed and processed outside the scheduled review cycle? If Component 4 specifies only a scheduled review cycle calibrated for low-frequency learning, this requirement is not satisfied.

(d) *Governance health remediation clause*. Does the agreement include a governance health remediation clause specifying notification obligations when health monitoring detects degradation below agreed thresholds, a remediation timeline, and event frequency reduction as an available governance remedy when health cannot be restored at the current operational tempo? If the agreement lacks a remediation clause, or if the clause specifies notification and termination without a frequency-reduction option, this requirement is not satisfied.

An agreement that fails any of (a)–(d) may be a well-constructed low-frequency governance agreement. It is not a governance agreement appropriate for the FAI relationship D2.71 and D2.34 jointly describe.
